FOREWORD

This report is published by the Aerospace Corporation, El Segundo, California, under Air Force Contract No. AF 04(695)-1001.

This report, which documents research carried out from September 1965 through February 1967, was submitted on 2 June 1967 to Capt. Ronald J. Starbuck (SSTRT) for review and approval.

The authors acknowledge with gratitude the contributions of Dr.

J. L. Selfridge who co-authored Section V, and the assistance of Miss

Pauline Parkin who prepared the checking program mentioned in Section II.

Approved

D. R. S. McColl, General Manager

Electronics Division

Publication of this report does not constitute Air Force approval of the report's findings or conclusions. It is published only for the exchange and stimulation of ideas.

Ronald J. Starbuck, Capt., USAF

Chieff Space Environment and

Electronics Branch

ABSTRACT

A compilation of results from research in number theory involving the use of a digital computer is presented. The research is related to characteristics of prime numbers, equal sums of powers of integers, differences of powers of integers, equal sums of fifth powers, and the classic problem of finding two equal sums of two biquadrates.

I. INTRODUCTION

This report describes research in the theory of numbers that involved the use of a digital computer.

Sections II and III concern characteristics of prime numbers and Sections IV and V problems in equal sums of powers of integers. In Section VI, the differences of powers of integers are discussed, while in VII and VIII two equal sums of fifth powers are considered. Sections IX and X provide the results of an investigation of the classic problem of finding two equal sums of two biquadrates.

The various sections of the report have been grouped for convenience.

Although the sections are related in subject, each one is self-contained.

II. ON FIRST APPEARANCE OF PRIME DIFFERENCES

A. DISCUSSION

There has long been interest in strings of consecutive composite numbers appearing among the natural numbers. Most elementary texts on number theory include a discussion of how arbitrarily large gaps between consecutive primes can be constructed, for example [1]. Such constructive techniques lead to rather large numbers, however, and lower occurrences have been studied [2], [3] to gain insight into the subject.

In 1961, Gruenberger and Armerding examined the first six million primes (up to P = 104, 395, 289) [4] on a computer and produced certain statistics covering these primes [5]. They tabulated the primes forming the lower boundary for the first appearance of prime differences of prescribed lengths, where all intervening numbers are composite, up to the limit of the primes list. The largest difference found between two consecutive primes was 220, and the smallest difference whose first appearance was not found was 186.

An algorithm for direct search for prime-differences (usable on a computer of limited storage capacity) proceeds as follows:

- a) Start at a known prime, say P_a, below which all differences of interest are known.
- b) Form P_a + D, where D is the smallest difference whose first appearance is unknown.
- c) From the point P_a + D, test the successively smaller numbers for primality by trial division or other technique until a prime P_b is found.
- d) If $P_b > P_a$, replace P_a by P_b and repeat the algorithm.
- e) If P_b = P_a, start testing at P_a + D, and proceed to successively larger numbers until a prime P_c is reached. P_c P_a is then a difference ≥ D between successive primes, and is recorded, unless such a difference has already occurred.

f) Update D, if necessary, to the next larger difference whose first appearance is unknown; replace P_a by P_c , and repeat the algorithm.

A computer program for the CDC 3200 was written to implement this algorithm, and Table I through the range $0 < P < 1.46 \times 10^9$ represents the data obtained from this program.

The algorithm itself guarantees that no difference of interest (i.e., \geq smallest difference whose first appearance is unknown) will escape notice, while a separate check was run on the data in Table I. This check took the form of another computer program which read the Table I data as input, established the primality of P_a and P_b by testing for divisibility by primes up to the square root of P_a or P_b , and explicitly exhibited all the prime factors of each odd number between the two primes. Thus, the differences listed are verified to be exactly as long as stated. Since all previous results in [5] were exactly duplicated (items of Table I for $D \leq 184$ and D = 196, 198, 210, 220), the data may be regarded as accurate.

The primality testing process was designed to operate without using an extensive table of primes, while, at the same time. being made as rapid as practicable. First, the numbers to be tested were required to be prime to 210. Since a sequence of consecutive numbers was being tested, a single division by 210 followed by a table lookup in a table of 210 positions sufficed to exclude all numbers not prime to 210. Each entry of the table actually pointed to the next eligible number to be tested. Secondly, division by a few small primes was used. Since the ranges of interest quickly exceeded the single precision word length of the computer (24 bits), the 48-bit hardware arithmetic of the machine was used. However, in order to avoid double precision division as long as possible, the numbers being tested were reduced to single precision by subtraction of self-adjusting multiples of groups of small primes prior to division by those primes. The final step was division by all odd numbers prime to 6 (by alternately adding 2, then 4, to an appropriate starting prime) and less than the square root of the number tested, in order to verify the primality of the end points for the algorithm, and to determine that

intervening numbers were composite. Of course, as soon as any eligible number being tested was found to be composite, it was rejected, and the next eligible number was selected for testing. Since there was no room in the program to store a table of pseudoprimes to the base 2, experiments with the converse of Fermat's Theorem to detect composite numbers were dropped when it was noted that the program spent the majority of its running time verifying the primality of the end points, rather than eliminating composite numbers between the end points.

With the availability of a larger computer memory in which to store a table of primes and their starting points with respect to a fixed field of bits, it becomes feasible to use a sieve technique for extending this search. However, with a very limited computer memory, the algorithm given above has the advantage of requiring only a table of previously found differences, and a starting point for each run, and thus could be used as a small background problem.

A program for the CDC 6600 was written to implement a sieve technique for generating and examining gaps in primes. This program occupied considerably more memory but ran significantly faster (partially due to an increase in computer speed) than the program described above. The sieve program allocated a block of computer memory in which consecutive bits represented the successive odd integers. A table of the first ten thousand primes was generated and stored by the program during initialization. Another table of starting points (i.e., index of the first bit in the field corresponding to a multiple of each prime in the stored table) for marking by each prime in the sieve field was also generated and saved. The program then cycled through successive bit fields marking bits corresponding to the odd composite numbers, then searched the field for gaps of interest. End effects at the boundaries of the sieve fields were noted so that gaps of interest would not be missed. Table I for 1.46 x 10^9 < P < 1.096 x 10^{10} presents the results obtained from this program.

In private correspondence Daniel Shanks suggested the possibility of extending Table I in [2] over the new differences found. Accordingly,

Table I shows $\log P_b/\sqrt{D-1}$, with each maximal gap D marked with an asterisk. Maximal gaps, according to Shanks, are those larger than any preceding gap in the sequence of primes. These data tend to support the conjectured relation in [2], namely that $\log P_b \sim \sqrt{D-1}$ for maximal gaps, and also, possibly, for all gaps at the point of their first appearance.

III. CONSECUTIVE PRIMES IN ARITHMETIC PROGRESSION

A. DISCUSSION

A. Schinzel and W. Sierpinski [1] conjectured that there exist arbitrarily long arithmetic progressions formed of consecutive prime numbers. Sierpinski stated in [2] that a progression of five consecutive primes had not yet been found. A direct computer search showed that the first such progression has the common difference d=30 and begins with the prime 9,843,019. The first progression of six consecutive primes begins with 121,174,811 and also has d=30. Up to the limit 3×10^8 there are 25 other progressions of five consecutive primes, all with d=30; there are no other progressions of six consecutive primes.

The reviewer points out that recently a much larger quintuplet, beginning with 10000024493, and again having d = 30, was recorded [3], but without reference to Sierpinski's remark. The smaller set that we found, and the single sextuplet, may still be worth recording.

IV. A COUNTEREXAMPLE TO EULER'S SUM OF POWERS CONJECTURE

A. DISCUSSION

A search was conducted on the CDC 6600 computer for non-trivial solutions in non-negative integers of the Diophantine equation

$$x_1^5 + x_2^5 + \cdots + x_n^5 = y^5$$
 , $n \le 6$. (1)

In general, to decompose t as the sum of n fifth powers, assume s is the largest. Then for each s in the range

$$\left(\frac{t}{n}\right)^{1/5} \le s \le t^{1/5}$$

a decomposition is sought in which $t - s^5$ is the sum of n - 1 fifth powers each $\le s^5$. Applying the algorithm repeatedly, a final decomposition is reached of the form

$$u = v^5 + w^5$$

in which $w \le v$ and each v in the range $(\frac{u}{2})^{1/5} \le v \le u^{1/5}$ is considered. Since $x^5 = x \pmod{30}$ for each integer x, we require $w = u - v \pmod{30}$. A precalculated table of fifth powers was employed and table lookup replaced the taking of fifth roots in determining limits on the x_i .

For n = 6, there are only ten primitive solutions of (1) in the range $y \le 100$ and these are given in Table I. The least two of these were obtained by A. Martin (Reference 1). Among the new solutions was

$$19^5 + 43^5 + 46^5 + 47^5 + 67^5 = 72^5$$

which is the least solution of (1) with n = 5. The search was then specialized to n = 5, and the four solutions given in Table II are the only primitive solutions over the range $y \le 250$. The third case (y = 107) is the least solution given by Sastry's identity (Reference 2)

$$(75 \text{ v}^5 - \text{u}^5)^5 + (\text{u}^5 + 25\text{v}^5)^5 + (\text{u}^5 - 25\text{v}^5)^5 + (10 \text{ u}^3\text{v}^2)^5 + (50 \text{ u}\text{v}^4)^5 = (\text{u}^5 + 75\text{v}^5)^5$$

for $\text{u} = 2$, $\text{v} = 1$.

The fourth case was the unexpected result

$$27^5 + 84^5 + 110^5 + 133^5 = 144^5$$

which is a counterexample to Euler's conjecture (Reference 3) that at least k positive k^{th} powers are required to sum to a k^{th} power, except for the trivial case of one k^{th} power: $y^k = y^k$. The search was again specialized to n = 4 over the range $y \le 750$, but no further primitive solutions exist in that range.

Table II. All Primitive Solutions of $x_1^5 + x_2^5 + x_3^5 + x_4^5 + x_5^5 + x_6^5 = y^5$, $y \le 100$

V. A SURVEY OF EQUAL SUMS OF LIKE POWERS

A. INTRODUCTION

The Diophantine equation

$$x_1^k + x_2^k + \cdots + x_m^k = y_1^k + y_2^k + \cdots + y_n^k \quad 1 \le m \le n$$
 (1)

has been studied by numerous mathematicians for many years and by various methods [1], [2]. We recently conducted a series of computer searches using the CDC 6600 to identify the sets of parameters k, m, n for which solutions exist and to find the least solutions for certain sets. This section outlines the results of the computation, notes some previously published results, and concludes with a table showing, for various values of k and m, the least n for which a solution to (1) is known.

We restrict our attention to $k \le 10$. We assume that the x_i and y_j are positive integers and $x_i \ne y_j$. We do not distinguish between solutions which differ only in that the x_i or y_j are rearranged. We will refer to (1) as (k, m, n) and say that a primitive solution to (k, m, n) is one in which no integer ≥ 1 divides all the numbers $x_1, x_2, \cdots, x_m, y_1, y_2, \cdots, y_n$. Putting

$$z = \sum_{i=1}^{m} x_i^k = \sum_{i=1}^{n} y_j^k$$

we order the primitive solutions according to the magnitude of z and denote the r^{th} primitive solution to (k, m, n) by $(k, m, n)_r$. Where we refer to the <u>range</u> covered in a search for solutions, we mean the upper limit on z. The notation $(x_1, x_2, \dots, x_m)^k = (y_1, y_2, \dots, y_n)^k$ means

 $\frac{m}{\sum_{i=1}^{n} x_{i}^{k}} = \sum_{j=1}^{n} y_{j}^{k}.$ Any parametric solution discussed does not include all solutions unless otherwise stated.

B. SQUARES AND CUBES

For k = 2 the general solution of the Pythagorean equation (2.1.2) is well known [2, pp. 165-170]. Many solutions in small integers and various parametric solutions have been given for (2.1.n) with $n \ge 3$. The general solution of (2.2.2) is known [2, p. 252]. Solutions to (2.2.n) with $n \ge 3$ and (2.m.n) with $n \ge 3$ are numerous.

The impossibility of solving (k. 1.2 with $k \ge 3$ is Fermat's last theorem, which has been established for $k \le 25000$ [3]. The general solution of (3.1.3) in rationals is attributed to Euler and Vieta [2, p. 550-554] and also produces all solutions to (3.2.2) if the arguments are properly chosen. There are many solutions in small integers and various parametric solutions to (3.1.n) with $n \ge 4$ and to (3.m.n) with $n \ge 2$ [2, pp. 563-565].

C. FOURTH POWERS

(4.1.n) -- For n = 3, no solution is known. M. Ward [4] developed congruential constraints which, together with some hand computing, allowed him to show that $x^4 = y_1^4 + y_2^4 + y_3^4$ has no solution if $x \le 10,000$. The authors extended the search on the computer using a similar method and verified that there is no solution for $x \le 220,000$. Ward showed that if $x^4 = y_1^4 + y_2^4 + y_3^4$ is a primitive solution, it may be assumed that x, $y_1 = 1 \pmod{2}$, y_2 , $y_3 = 0 \pmod{8}$ and either $x - y_1$ or $x + y_1$ is $y_1 = 0 \pmod{1024}$. Also $x \ne 0 \pmod{5}$, or else all y_1 would be $y_1 = 0 \pmod{5}$, since $y_1 = 0 \pmod{5}$ according as $y_1 = 0 \pmod{5}$. The computer program generated

all numbers $M = (x^4 - y_1^4)/2048$ with $0 < y_1 < x$, x prime to 10 and $y_1 = \pm x$ (mod 1024). Tests were applied to $M = (y_2/8)^4 + (y_3/8)^4$ to reject cases in which a solution would not be primitive or M could not be the sum of two biquadrates. If M passed all the tests, its decomposition was attempted by trial using addition of entries in a stored table of biquadrates (27500 entries for $x \le 220,000 = 8.27500$). The tests were

- (1) M must be $\equiv 0$, 1, or 2 (mod 16) and (mod 5)
- (2) M must not be = 7, 8, or 11 (mod 13) and must not be = 4, 5, 6, 9, 13,22 or 28 (mod 29)
- (3) x and y_1 must not both be divisible by an odd prime $p \equiv 3$, 5 or 7 (mod 8) for if so, p^4 divides M, p divides y_2 and y_3 , and the solution is not primitive
- (4) M must not have a factor p where p is an odd prime not

 1 (mod 8) unless p⁴ also divides M. In this case p divides y² and y³, and in the decomposition by trial M can be replaced by M/p⁴ (here tests were made only for p < 100).</p>

Of approximately 19,200,000 initial values of M, only 22,400 required the trial decomposition.

For n = 4, R. Norrie [5] found the smallest solution (353)⁴ = (30, 120, 272, 315)⁴.

J. O. Patterson [28] found (4, 1, 4)₂ and J. Leech [6] found the next six primitive solutions on the EDSAC 2 computer. S. Brudno [7] gave another primitive solution, the 14th in our Table IV. The authors exhaustively searched the range 8002⁴ using Leech's method of finding the 23 primitives listed in Table IV. No parametric solution has been found for (4, 1, 4), although the general solution is known for (3, 1, 3) and a parametric solution (discussed later) is known for (5, 1, 5).

23	7703	2230	3196	5620	6995	

For $n \ge 5$ there exist many solutions in small integers. $(4.1.5)_1$ is $(5)^4 = (2,2,3,4,4)^4$. Several parametric solutions to (4.1.5) are known due to E. Fauquembergue [8], C. Haldeman [9], and A. Martin [10].

(4.2.n) -- For n = 2 the least solution is $(59, 158)^4 = (133, 134)^4$. Euler [11] gave a two-parameter solution and A. Gerardin [12] gave an equivalent but simpler form of this solution. Several of the smaller primitive solutions were found by Euler, A. Werebrusow, and Leech [13], and a recent computer search by Lander and Parkin [14] extended the list of known primitives to 31. More recently we have increased this to a total of 46 primitives by a complete search of the range 5.3 x 10^{16} and the 15 new primitives are listed in Table V. The general solution is not known.

For $n \ge 3$ there are many small solutions. $(4.2.3)_1$ is $(7,7)^4 = (3,5,8)^4$. Several parametric solutions are known for (4.2.3) due to Gerardin [15] and F. Ferrari [16].

(4. m. n) -- For m \geq 3, solutions in small integers are numerous. Parametric solutions to (4. 3. 3) were given by Gérardin [17] and Werebrusow [18]. $(4. 3. 3)_1$ is $(2, 4, 7)^4 = (3. 6, 6)^4$.

D. FIFTH POWERS

(5. 1. n) -- For n = 3, no solution is known. Lander and Parkin [19], [20] found (5. 1. 4)₁ to be $(144)^5 = (27, 84, 110, 133)^5$. This disproved Euler's conjecture [2, p. 648] that (k. 1. n) has no solution if 1 < n < k. No further primitive solutions to (5. 1. 4) exist in the range up to 765^5 .

For n = 5, S. Sastry and S. Chowla [21] obtained a two-parameter solution yielding $(107)^5 = (7, 43, 57, 80, 100)^5$ as its minimal primitive; this solution

Table V Primitive Solutions of (4. 2. 2) for 7. 5 x $10^{15} \le z \le 5$. 3 x 10^{16} z = $x_1^4 + x_2^4 = y_1^4 + y_2^4$

^{*}For solutions to (4, 2, 2) for i = 1 to 31 see Lander and Parkin [14].

^{**} This solution was found by Euler [2, p. 644].

is $(5.1.5)_3$. Lander and Parkin [20] found $(5.1.5)_1$ and $(5.1.5)_2$ to be $(72)^5 = (19, 43, 46, 47, 67)^5$ and $(94)^5 = (21, 23, 37, 79, 84)^5$. More recently we searched the range up to 599^5 and found the twelve primitive solutions given in Table VI.

For $n \ge 6$ there are solutions in moderately small integers. $(5.1.6)_1$ is $(12)^5 = (4,5,6,7,9,11)^5$ found by A. Martin [22]. The first eight primitive solutions to (5.1.6) are given in [20]. $(5.1.7)_1$ is $(23)^5 = (1,7,8,14,15,18,20)^5$.

(5. 2. n) -- No solution is known for $n \le 3$. An exhaustive search by the authors verified that there is no solution to (5. 2. 2) in the range up to 2. 8 x 10^{14} or to (5. 2. 3) in the range up to 8 x 10^{12} . Sastry's parametric solution for (5. 1. 5) mentioned above gives for certain values of its arguments solutions to (5. 2. 4), the smallest being $(12, 38)^5 = (5, 15, 25, 37)^5$, which is $(5. 2. 4)_2$. K. Subba Rao [23] found $(3, 29)^5 = (4, 10, 20, 28)^5$, which is $(5. 2. 4)_1$. Table VII lists the ten primitives which exist in the range up to 2×10^{10} .

For $n \ge 5$, there are solutions in moderately small integers, $(5.2.5)_1$ is $(1.22)^5 = (4.5, 7.16, 21)^5$ due to Subba Rao [23]. We give the first six primitives for (5.2.5) in Table VIII.

(5.3.n) -- The first solution known for n = 3 was $(49,75,107)^5 = (39,92,100)^5$ due to A. Moessner [29]; this is $(5.3.3)_5$. H. P. F. Swinnerton-Dyer gave two separate, two-parameter solutions [30]. We give the 45 primitives in the range up to 8×10^{12} in Table IX. For $n \ge 4$, solutions in small integers are plentiful. $(5.3.4)_1$ is $(3.22,25)^5 = (1.8,14.27)^5$ due to Subba Rao [23]. A two-parameter solution to (5.3.4) was given by G. Xeroudakes and A. Moessner [24].

(5. m. n) -- If $m \ge 4$, there are many solutions in small integers. (5. 4. 4)₁ is $(5,6,6,8)^5 = (4,7,7,7)^5$ due to Subba Rao [23]. Several parametric solutions to (5. 4. 4) were found by Xeroudakes and Moessner [24]. The first triple coincidence of four fifth powers is $1479004544 = (3,48,52,61)^5 = (13,36,51,64)^5 = (18,36,44,66)^5$.

In the subsequent discussion we adopt a notation borrowed from the field of partitions, writing x^r to signify the term x repeated r times in the expression in which it appears. Table X uses this notation, giving (k.m.n)₁ where known and referencing solutions in other tables. Table X also shows for certain (k.m.n) the range which has been searched on the computer exhaustively.

For the remainder of the equations (k. m. n) which are discussed, we note in the text only the limits searched, interesting features, and methods employed, specific solutions are given in Table X.

E. SIXTH POWERS

(6.1. n) -- No solution is known for $r \le 6$. We consider the cases of r = 6, 7, and 8 in lescending order. To solve (6.1.8), $x^6 = \sum_{1}^{8} y_1^6$, note that $u^6 \equiv 0$ or 1 (mod 9) according to whether $u \equiv 0$ or $u \not\equiv 0$ (mod 3). Then if $x \equiv 0$ (mod 3), all $y_1 \equiv 0$ (mod 3) and the solution is not primitive. Therefore, take x and exactly one of the y_1 (say y_1) prime to 3. Then $(x^6 - y_1^6)/3^6 = \sum_{1}^{8} (v_1/3)^6$ is an integer (which is true if and only if $y_1 \equiv \pm x \pmod{243}$) to be decomposed by trial as the sum of 7 sixth powers. In Table XI, we

14	623	12	90	114	114	273	306	492	592

give the 14 smallest primitives found by this method; $(6.1.8)_1$ is $(251)^6 = (8, 12, 30, 78, 102, 138, 165, 246)^6$.

For (6.1.7), $x^6 = \frac{7}{1} y_1^6$, note that $u^6 = 0$ or 1 (mod 8) according as u is even or odd. Then for a primitive solution, x and exactly one of the y_1 are odd. The argument for (6.1.8) modulo 9 applies and x is prime to 6, y_1 (say) is prime to 3, and either y_1 is odd or another y_1 (say y_2) is odd. In the first case $y_1 = \pm x \pmod{243}$ and (mod 32), and $(x^6 - y_1^6)/6^6 = \frac{7}{2} (y_1/6)^6$ is an integer to be decomposed by trial as the sum of 6 sixth powers. In the second case $y_1 = \pm x \pmod{243}$, $y_2 = \pm x \pmod{32}$ and $(x^6 - y_1^6 - y_2^6)/6^6 = \frac{7}{2} (y_1/6)^6$ must be an integer (certain combinations x, y_1 , y_2 satisfying the congruences are rejected), which is decomposed by trial as the sum of 5 sixth powers. The only solution for $x \le 1536$ is $(6.1.7)_1$, $(1141)^6 = (74,234,402,474,702,894,1077)^6$, which is obtained in the second case.

For (6.1.6), $x^6 = \sum_{1}^{6} y_1^6$ note that $u^6 \equiv 0$ or 1 (mod 7) according as $u \equiv 0$ or $u \not\equiv 0$ (mod 7). Then for a primitive solution, x and exactly one of the y_1 (say y_1) are prime to 7. This implies $y_1 \equiv \pm x$, $\pm qx$ or $\pm q^2x$ where q = 34968 is a primitive sixth root of unity (mod $7^6 = 117649$). Now the foregoing arguments modulo 8 and modulo 9 apply. and there are five cases.

- (1) If $y_1 = \pm 1 \pmod{6}$, then $y_1 = \pm x \pmod{243}$ and $\pmod{32}$ and $(x^6 y_1^6)/42^6 = \sum_{i=2}^{6} (y_i/42)^6$ is an integer to be decomposed by trial as the sum of 5 sixth powers.
- (2) If $y_1 = \pm 2 \pmod{6}$, then $y_1 = \pm x \pmod{243}$ and another of the y_1 (say y_2) is odd. Then $y_2 = 0 \pmod{3 \cdot 7}$, $y_2 = \pm x \pmod{32}$, and $(x^6 y_1^6 y_2^6)/42^6 = \sum_{3}^{6} (y_1/42)^6$ is the sum of 4 integral sixth powers.

- (3) If $y_1 \equiv 3 \pmod{6}$, then $y_1 \equiv \pm x \pmod{32}$ and another of the y_i (say y_2) is prime to 3, $y_2 \equiv 0 \pmod{2 \cdot 7}$, and $y_2 \equiv \pm x \pmod{243}$. In case (2), $(x^6 y_1^6 y_2^6)/42^6$ is an integer and is the sum of 4 sixth powers.
- (4) If $y_1 \equiv 0 \pmod{6}$, another of the $y_1 \pmod{y_2}$ is prime to 3, $y_2 \equiv 0 \pmod{7}$, and $y_2 \equiv \pm x \pmod{243}$. If y_2 is odd, then $y_2 \equiv \pm x \pmod{32}$, and as in cases (2) and (3) $(x^6 y_1^6 y_2^6)/42^6$ is the sum of 4 sixth powers. If y_2 is even, we have case (5).
- (5) Another of the y_i (say y_3) is odd, $y_3 = 0$ (mod $3 \cdot 7$), $y_3 = \pm x$ (mod 32), and $(x^6 y_1^6 y_2^6 y_3^6)/42^6 = \sum_{i=1}^{6} (y_i/42)^6$ is an integer to be decomposed as the sum of 3 sixth powers.

The search for a solution to (6.1.6) was carried exhaustively by this method through the range $x \le 38314$, and there is no solution in this range.

A. Martin [25] gave a solution to (6.1.16); Moessner [26] gave solutions to (6.1.n) for n = 16, 18, 20 and 23. For $n \ge 11$, it is not difficult to find solutions in small integers.

(6.3.n) -- Subba Rao [23] found the solution $(3,19,22)^6 = (10,15,23)^6$, which is $(6.3.3)_1$. In Table XII we give the remaining 9 primitive solutions which exist in the range up to 2.5 x 10^{14} . It is interesting to note that each of the solutions except the sixth is also a solution to (2.5,3). Table XIII gives the five primitive solutions to (6.3.4) which exist in the range up to 2.9×10^{12} .

(6. m. n) -- If m is ≥ 4 , solutions in small integers can be found readily. Subba Rao [23] gave (6. 4. 4)₁ (see Table X. The first triple coincidence of four sixth powers is $1885800643779 = (1, 34, 49, 111)^6 = (7, 43, 69, 110)^6 = (18, 25, 77, 109)^6$.

Table XII

Primitive Solutions of (6.3.3) for $z \le 2.5 \times 10^{14}$ $z = \sum_{j=1}^{3} x_{j}^{6} = \sum_{j=1}^{3} y_{j}^{6}$

F. SEVENTH POWERS

 $(7.2.10)_2$ is $(2,27)^7 = (4,8,13,14^2,16,18,22,23^2)^7 = <math>(7^2,9,13,14,18,20,22^2,23)^7$ which is a double primitive and reduces to the solution $(7.5.5)_2$.

(7.5.n) -- Table XIV lists the 17 primitive solutions to (7.5.5) which exist in the range up to 4.0×10^{12} .

G. EIGHTH POWERS

(8.1.n) -- We found a parametric solution to (8.1.17), $(2^{8k+4}+1)^8 = (2^{8k+4}-1)^8 + (2^{7k+4})^8 + (2^{k+1})^8 + 7 [(2^{5k+3})^8 + (2^{3k+2})^8]$ which for k = 0 yields (8.1.17)₁. This was the solution used by Sastry [21] in developing a parametric solution to (8.8.8). The computer program used in searching for solutions to (8.1.n) was based on the congruences $x^8 \equiv 0$ or 1 (mod 32) according to whether $x \equiv 0$ or 1 (mod 2), so that primitive solutions to $x^8 = \frac{n}{1} y_j^8$ with n < 32 must have x and (say) y_1 both odd. Then $x^8 - y_1^8$ is divisible by 2^8 , which implies $x \equiv \pm y_1 \pmod{32}$, and $(x^8 - y_1^8)/256$ is decomposed as the sum of n - 1 eighth powers by trial.

Solutions to (8.5.5) and (8.9.9) were found by A. Letac [27].

H. NINTH AND TENTH POWERS

Computations performed by the authors for (9. m. n) and (10. m. n) are the basis for the data shown in the last two columns of Table XV, except for a solution to (10. 7. 7) given by A. Moessner [29]. Due to computer word length limitations the calculations were not extended to large values of the arguments.

Table XIV

I. CONCLUDING REMARKS

Let N (k, m) be the smallest n for which (k, m, n) is solvable. In Table XV we show the upper bound to N based on the results just presented. Each column is terminated when a solution to (k, m, m) has been found. It appears likely that whenever (k, m, m) is solvable, so is (k, r, r) for any r > m. Some questions are:

- a. Is $N(k, m+1) \le N(k, m) \le N(k+1, m)$ always true?
- b. Is (k, m, n) always solvable when m + n > k?
- c. Is it true that (k, m, n) is never solvable when m + n < k?
- d. For which k, m, n, such that m + n = k, is (k, m, n) solvable?

The results presented in this section tend to support an affirmative answer to (c). Question (d) appears to be especially difficult. The only solvable cases with m + n = k known at present are (4.2.2), (5.1.4), and (6.3.3).

In this section we have made a computational attack on the problem of finding a sum of n kth powers which is also the sum of a smaller number of kth powers. In many of the cases considered, especially for the larger values of k, we have undoubtedly not obtained the best possible results, but the amount of computing needed to do this would seem to be overwhelming.

We believe that the main result of this section is the presentation of results on a family of Diophantine equations which have largely been considered separately in the past. We hope that this presentation offers greater insight into the nature of the function N (k, m) and that the future efforts will be directed toward reducing the upper bounds for this function.

VI. DIFFERENCES OF POWERS

A. INTRODUCTION

In this document we use the word <u>power</u> to denote a number of the form x^m where x and m are positive integers and m > 1. We consider which positive integers z can be expressed as the difference of two powers; that is,

$$z = x^{m} - y^{n}, z > 0.$$
 (1)

We have employed the CDC 6600 computer to find all solutions to (1) in which $z \le 1000$ and $y^n < x^m \le 10^{24}$.

A direct method can be used to solve (1) for $z \le D$ and $y^n < x^m \le L$. For x > 1, consider the nth powers nearest to x^{m} . If u is the greatest integer in $x^{m/n}$, these are u^n , $(u \pm 1)^n$, $(u \pm 2)^n$, ..., If $h \ge 0$ and $z = x^m$. $(u - h)^n \le D$, we obtain a solution. If $x^m - 1 \le D$, then each h with $0 \le h \le x - 1$ is an acceptable value. Similarly, for $z = (u + h)^n - x^m \le D$, $h \neq 0$, we obtain a solution. By examining the successive values h = 0, 1, 2, ..., we obtain all solutions in which the power x appears; a simple test indicates where to terminate each sequence. If n = m, it is only necessary to consider $z = x^{m} - (x - h)^{m}$ for h = 1, 2, 3, ..., as long as $z \le D$, or until h = x - 1. In this case an upper limit to x is the least integer X such that $(X + 1)^m - X^m > D$. Since for m = pq and n = rs, $x^m - y^n = (x^p)^q - (y^r)^s$, if the foregoing procedure is carried out for all values of x with $x^{m} \le L$, then only prime exponents m and n, with $n \le m$, need be examined. For $L = 10^{24}$ and D = 1000, it is necessary to consider 500 squares (since $501^2 - 500^2 > 1000$), $10^{24/3} = 10^8$ cubes, 63095 = [10^{24/5}] fifth powers, and so forth. The largest exponent m tried was 79, because $2^{80} > 10^{24}$.

Since the number of cubes to be examined in solving $z = \pm (x^3 - y^2)$ is so large, a special method was employed. (This was desirable especially since the larger values of x^3 and y^2 are integers of up to 24 digits, necessitating the use of double precision arithmetic.) If x is large compared to D, then $x^{3/2}$ must be very nearly an integer. For, setting $x^{3/2} = y + a$ where y is an integer and |a| < 1, we have

$$D \ge |x^3 - y^2| = |(y + a)^2 - y^2| = |a(2y + a)| > |a|(2y - 1),$$

so that $|a| < \frac{D}{2y-1} < \frac{D}{2x^{3/2}-3}$. If x > 90,000 and D = 1000, $|a| < 2 \times 10^{-5}$. We can therefore require that the fractional part of $x^{3/2}$ be very close to 0 or 1 before proceeding to compute the difference between x^3 and the squares nearest to x^3 .

Now let $x - t^2 + u$ where t, u are integers, t > 0 and $1 \le u \le 2t$. Then

$$x^{3/2} = t^3 \left(1 + \frac{u}{t^2}\right)^{3/2} = t^3 + \frac{3tu}{2} + \frac{3u^2}{8t} - \frac{u^3}{16t^3} + \frac{3u^4}{128t^5} - \frac{3u^5}{256t^7} + \dots$$
 (2)

If $\lambda(t, u) = 0$ when tu is even and = 1/2 when tu is odd, the fractional part of $x^{3/2}$ is the same as the fractional part of $f(t, u) = \lambda(t, u) + \frac{3u^2}{8t} - \frac{u^3}{16t^3}$ with an error not exceeding $\frac{3u^4}{128t^5} \le \frac{3}{128} \cdot \frac{16t^4}{t^5} = \frac{3}{8t}$. If x > 90,000, then t > 300 and this error is < 0.00125. The direct method was used for $x \le 90,000$ and, for $90,000 < x \le 10^8$, each x was rejected unless the fractional part of f(t, u) fell either in the range (0,0.0013) or (0.9987, 1), in which case the direct method was applied to x.

The power series expansion for $x^{3/2}$, (2), leads to the following sets of polynomials x, y, z such that $z = x^3 - y^2$ is (relatively) small.

$$x = t^2 + u$$
, $y = t^3 + \frac{3tu}{2}$, $z = \frac{3}{4}t^2u^2 + u^3$, where tu is even; (3)

$$t = 6p^2/d$$
 where d divides $6p^2$
 $u = 4p$
 $x = t^2 - u$, $y = t^3 - \frac{3}{2}tu + d$, $z = 8p^3 - d^2$.

For example, (3) gives for u = 1, t = 2, x = 5, y = 11, $z = x^3 - y^2 = 4$, and (4) gives for d = 1, p = 5, x = 22480, y = 3370501, $z = x^3 - y^2 = 999$.

B. RESULTS

There are 2895 solutions to (1) with $1 \le z \le 1000$ and $y^n < x^m \le 10^{24}$. Of these, 274 solutions have $z \le 100$ and these are given in Table XVI. Some characteristics of the larger set of solutions are given in the following discussion.

Let G(t) denote the number of solutions to (1) for $0 < z \le t$. S. Pillai conjectured [1] that G(t) is finite for all t > 0. We give in Table XVII a tabulation of F(t), a lower bound to G(t), obtained by counting the solutions for which $x^m \le 10^{24}$. F(t) is approximately linear in the interval $0 < t \le 1000$, and for $100 \le t \le 1000$ and we have 2.7 < F(t)/t < 2.9.

To suggest that G(t) is indeed finite and is closely approximated by F(t) we give in Table XVIII the number of solutions to (1) with $z \le 1000$ in which x^m has k digits, for $k = 1, 2, 3, \ldots, 18$. (There are no solutions with $19 \le k \le 24$.) It seems likely that the total number of solutions for $z \le 1000$ in which x^m exceeds 10^{24} is a small integer or zero.

Number of Solutions, N(k), with k Digits

k	1	2	3	4	5	6	7	8	9	
N(k)	6	72	742	963	605	296	72	47	33	
k	10	11	12	13	14	15	16	17	18	
N(k)	20	16	8	4	3	3	1	2	2	

 $\label{eq:table_XIX} \textbf{.}$ Number of Values R(k) of z for Which There Are k Solutions

k	0	1	2	3	4	5	6	7	8	9	10	11	12	13	
R(k)	138	124	223	173	158	69	55	25	16	5	8	3	1	2	

For each $z \le 1000$ there are at most 13 solutions in the range considered. We give in Table XIX the number of values of z for which there are k solutions, $0 \le k \le 13$. The two values of $z \le 1000$ with the maximum number of representations as the difference of two powers are

$$225 = 17^{2} - 2^{6} = 5^{4} - 20^{2} = 39^{2} - 6^{4} = 113^{2} - 112^{2} = 21^{2} - 6^{3}$$

$$= 35^{2} - 10^{3} = 60^{2} - 15^{3} = 165^{2} - 30^{3} = 465^{2} - 60^{3} = 2415^{2} - 180^{3}$$

$$= 6159^{2} - 336^{3} = 6576^{2} - 351^{3} = 611085363^{2} - 720114^{3};$$

and

$$775 = 28^{2} - 3^{2} = 30^{2} - 5^{3} = 10^{3} - 15^{2} = 80^{2} - 75^{2} = 19^{3} - 78^{2} = 20^{3} - 85^{2}$$

$$= 264^{2} - 41^{3} = 10^{5} - 315^{2} = 388^{2} - 387^{2} = 70^{3} - 585^{2} = 80^{3} - 715^{2}$$

$$= 16750^{3} - 2167815^{2} = 26530^{3} - 4321215^{2}.$$

The 138 values of z for which (1) has no solutions (in the range covered) are given in Table XX. All these are of the form 4k + 2, since any other positive integer is the difference of two squares (except $1 = 3^2 - 2^3$ and $4 = 2^3 - 2^2$).

In Table XXI we give the solution to (1) in largest integers, over the range considered, for each pair of prime values m, n. Where there is no entry for a given pair m, n, all positive differences $x^m - y^n$ exceed 1000. If the upper limit on z is increased to 10,000, the only additional solutions in largest integers obtained in which either m or n exceeds 19 are $9796 = 2898^2 - 2^{23}$, $1792 = 2^{23} - 2896^2$ and $4633 = 46341^2 - 2^{31}$. (Note: $z = 4002 = 2897^2 - 2^{23}$ is not in largest integers x, y for a particular pair m, n.)

The equation $\pm z = x^3 - y^2$ was studied on a computer by M. Lal, M. Jones and W. Blundon [2], who reported 8593 solutions in the range $|z| < 10^4$ and $x < 4.64 \times 10^6$. Since negative values for x were allowed, the results

17	2	2	361	751
2	17	11 364	3	335
19	2	2	724	112

are not exactly comparable to those given here. In our calculations we recorded differences of powers up to $z \le 10,000$ and can state that for $4.64 \times 10^6 \le x \le 10^8$ there are only four additional solutions:

$$-3753 = 5024238^{3} - 11261735055^{2}$$

$$7670 = 6369039^{3} - 16073515093^{2}$$

$$-6856 = 27564105^{3} - 144715764559^{2}$$

$$-1090 = 28187351^{3} - 149651610621^{2}$$

Catalan's conjecture, that equation (1) with z = 1 has only one non-trivial solution, is a problem studied much but not yet completely solved.

J. W. S. Cassels [3] and K. Inkeri [4] have made recent contributions to the theory of this problem.

C. ARITHMETIC PROGRESSIONS

If $z = x^m - y^n = y^n - w^k$, then the three powers w^k , y^n , x^m form an arithmetic progression with common difference z. The set of solutions to (1) was examined to find values of z for which there were two solutions (or more) having a common term. There are thirty-one progressions of three terms identified in this way, listed in Table XXII. There are no progressions of four terms in the range covered.

A. Guibert [5] gave the general solution for three relatively prime squares a^2 , b^2 , c^2 in arithmetic progression:

$$a = \pm (p^2 - q^2 - 2pq), b = p^2 + q^2, c = p^2 - q^2 + 2pq,$$

where p and q are relatively prime and not both are odd. Euler [6] proved that four distinct squares cannot be in arithmetic progression.

There are infinitely many progressions of the form a^2 , b^n , c^2 where n > 2. For, if b is the sum of two squares, so is $2b^n = a^2 + c^2$. The smallest examples are 81, 125, 169 and 25, 125, 225 derived from $2 \cdot 5^3 = 9^2 + 13^2 = 5^2 + 15^2$.

It has been shown that three distinct positive cubes [7] or biquadrates [8] cannot be in arithmetic progression. There are no known instances of three distinct positive n^{th} powers in arithmetic progression for $n \ge 5$. That is, $a^n + b^n = 2c^n$ has no known non-trivial solutions for $n \ge 3$.

A. Makowski [9] proved that there is no progression of three powers with the common difference 1.

It is possible to construct any number of arithmetic progressions of arbitrary length in which each term is a power. To show this, let $x_1^1, x_2^2, \ldots, x_r^r$ be a progression of powers with $r \ge 2$ terms and common difference $d \ne 0$. Then, if $y = x_r^r + d$ is not already a power, let c be the least common multiple of a_1, a_2, \ldots, a_r and let $c = a_ib_i$ for $1 \le i \le r$. Then the sequence

$$y^{c}x_{1}^{a}$$
, $y^{c}x_{2}^{a}$, ..., $y^{c}x_{r}^{a}$, y^{c+1}

is the same as

$$(y^{b_1}x_1)^{a_1}$$
, $(y^{b_2}x_2)^{a_2}$, ..., $(y^{b_r}x_r)^{a_r}$, y^{c+1} ,

a progression of powers with r + 1 terms and common difference $y^c d$. For example, from the progression 8, 36, 64 = 2^3 , 6^2 , 2^6 whose next term is 64 + 28 = 92, we can derive the progression

$$92^{6} \cdot 2^{3}, 92^{6} \cdot 6^{2}, 92^{6} \cdot 2^{6}, 92^{7} = (2 \cdot 92^{2})^{3}, (6 \cdot 92^{3})^{2}, (2 \cdot 92)^{6}, 92^{7}$$

of four terms. This method produces progressions in which all terms have a common factor > 1. It is not known whether there exists a progression of powers of more than three terms for which no integer > 1 divides every term. We have seen that if there is such a progression, the common difference must exceed 1000 or one of the terms must exceed 10^{24} .

VII. TWO EQUAL SUMS OF FOUR FIFTH POWERS

A. DISCUSSION

We shall derive three parametric solutions of the Diophantine equation

$$A_1^5 + A_2^5 + A_3^5 + A_4^5 = B_1^5 + B_2^5 + B_3^5 + B_4^5$$
 (1)

for which we also use the notation $(A_1, A_2, A_3, A_4)^5 = (B_1, B_2, B_3, B_4)^5$. By generating and sorting numbers of the form $A_1^5 + A_2^5 + A_3^5 + A_4^5$ on a digital computer it was observed that (1) has many solutions in moderately small positive integers and that a large proportion of these solutions satisfy the additional conditions

$$A_1 + A_2 = B_1 + B_2$$
 $A_3 + A_4 = B_3 + B_4$. (2)

For example, the solution of (1) in least integers is $(5.6, 6, 8)^5 = (4, 7, 7, 7)^5$, which also satisfies (2), since 5 + 6 = 4 + 7, 6 + 8 = 7 + 7.

If we set

$$A_{1} = u_{1} + v_{1} + w_{1} \qquad B_{1} = u_{1} + v_{1} - w_{1}$$

$$A_{2} = u_{1} - v_{1} - w_{1} \qquad B_{2} = u_{1} - v_{1} + w_{1}$$

$$A_{3} = u_{2} + v_{2} - w_{2} \qquad B_{3} = u_{2} + v_{2} + w_{2}$$

$$A_{4} = u_{2} - v_{2} + w_{2} \qquad B_{4} = u_{2} - v_{2} - w_{2}$$
(3)

it follows at once that (3) is a solution of (2). Equation (1) will also be satisfied provided that

$$u_1v_1w_1 (u_1^2 + v_1^2 + w_1^2) = u_2v_2w_2 (u_2^2 + v_2^2 + w_2^2).$$
 (4)

For the least solution, $(u_1, v_1, w_1) = (11.2, 1)$, $(u_2, v_2, w_2) = (14, 1, 1)$, and $(11.2 \cdot 1)(11^2 + 2^2 + 1^2) = 22 \cdot 126 = 2 \cdot 11 \cdot 9 \cdot 14 = 14 \cdot 198 = 14 \cdot 1 \cdot 1)(14^2 + 1^2 + 1^2)$.

The first two parametric solutions are obtained by applying to (4) a well-known geometric method related to plane curves of the third degree. If P is a rational point on a curve C, and if the tangent to C at P intersects C again, the intersection has rational coordinates. If C has an asymptote A with rational slope and the line through P parallel to A intersects C again, this intersection is also a rational point.

Consider the Cartesian curve C with equation

$$xab(x^2 + a^2 + b^2) = yac(y^2 + a^2 + c^2)$$
 $abc \neq 0$, (5)

which has an asymptote $bx^3 = cy^3$ of rational slope m, provided $b = cm^3$. Then x = c, y = b is trivially a rational point P on C. The line through P with slope m intersects C again in the point with coordinates

$$x = [a^2 + c^2 + c^2 m^2 (m^2 - 1)^2]/3m^2c$$

 $y = mx + mc (m^2 - 1).$

After clearing of fractions, this gives the following parametric solution to (4):

$$u_{1} = a^{2} + (m^{6} - 2m^{4} + m^{2} + 1) c^{2}$$

$$v_{1} = 3m^{5} c^{2}$$

$$w_{1} = 3m^{2} ac$$

$$u_{2} = ma^{2} + (m^{7} + m^{5} - 2m^{3} + m) c^{2}$$

$$v_{2} = 3m^{2} c^{2}$$

$$w_{3} = 3m^{2} ac$$
(6)

For each rational m there results a solution to (1) in homogeneous polynomials of the second degree in two variables. The least primitive solutions to (1) produced by (6) with integer arguments have

(m, a, c) = (2, 1, 1) and (2, 1, 3) which give $(23, 73, 74, 74)^5 = (35, 61, 62, 86)^5$ and $(7, 70, 89, 94)^5 = (43, 53, 58, 106)^5$, respectively.

Next, the tangent to C at P has the equation

$$y = k_1 x + k_2 \tag{7}$$

where $k_1 = \frac{b(a^2 + b^2 + 3c^2)}{c(a^2 + 3b^2 + c^2)}$, $k_2 = b - k_1c$

and intersects C again in a point with abscissa

$$x = \frac{3c k_1^2 k_2}{b - ck_1^3} - 2c.$$
 (8)

Equations (7) and (8) together with

$$u_1 = x$$
 $v_1 = b$ $w_1 = a$ (9)
 $u_2 = y$ $v_2 = c$ $w_2 = a$

provide another solution to (4) in the three parameters a, b, c. The two least primitive solutions to (1) produced by (9) have (a, b, c) = (2,1,5) and (2,1,3), giving respectively $(11,17,22,28)^5 = (7,21,24,26)^5$ and $(28,30,39,45)^5 = (24,34,41,43)^5$.

A third solution is derived by taking (4) together with the additional condition

$$u_1 v_1 w_1 = u_2 v_2 w_2$$
, (10)

which implies (for non-trivial solutions)

$$u_1^2 + v_1^2 + w_1^2 = u_2^2 + v_2^2 + w_2^2$$
.

(When (3), (10), and (11) are satisfied, $(A_1, A_2, A_3, A_4)^n = (B_1, B_2, B_3, B_4)^n$ for n = 1, 3 and 5.) A solution of (11) can be written

$$u_1 = x + a$$
 $v_1 = y - b$ $w_1 = z - c$
 $u_2 = x - a$ $v_2 = y + b$ $w_2 = z + c$ (12)

where a, b, c, x, y, z are any rational numbers satisfying the single condition

$$ax = by + cz. (13)$$

Substituting (12) into (10) and using (13) to eliminate x gives

$$(yz) b^2 + c(y^2 + z^2 - a^2) b + yz(c^2 - a^2) = 0.$$
 (14)

If b is rational, the discriminant of this quadratic equation must be a square, say k^2 . This condition may be written

$$c^{2}(y+a+z)(y+a-z)(y-a+z)(y-a-z)=(k+2ayz)(k-2ayz).$$
 (15)

Assuming that

$$k + 2ayz = c (y + a + z) (y - a + z)$$

 $k - 2ayz = c (y + a - z) (y - a - z)$, (16)

we find using (14) and (13) that

$$a = c$$
, $k = c (y^2 + z^2 - c^2)$, $b = -\frac{c}{yz} (y^2 + z^2 - c^2)$,
 $x = \frac{c^2 - y^2}{z^2}$. (17)

After clearing of fractions and making a slight change in notation, the resulting solution to (4) is

$$u_1 = b (c^2 - b^2 + ac)$$
 $u_2 = b (b^2 - c^2 + ac)$
 $v_1 = (a + c) (b^2 - c^2 + ac)$ $v_2 = (a - c) (c^2 - b^2 + ac)$ (18)
 $w_1 = ab (a - c)$ $w_2 = ab (a + c)$.

The primitive solutions to (1) in integers not exceeding 50 produced by (18) are given in Table XXIII. In preparing this table terms were transposed so as to be written positively, and common factors were removed.

The following two-parameter solution to (1) was given by G. Xeroudakes and A. Moessner [1]:

$$A_{1} = -p^{2} + 4pq + 9q^{2}$$

$$A_{2} = 3p^{2} + 12pq + 21q^{2}$$

$$A_{3} = p^{2} + 8pq + 3q^{2}$$

$$A_{4} = 3p^{2} + 12pq + 21q^{2}$$

$$B_{1} = 3p^{2} + 16pq + 17q^{2}$$

$$B_{2} = -p^{2} + 13q^{2}$$

$$B_{3} = p^{2} + 12pq + 23q^{2}$$

$$B_{4} = 3p^{2} + 8pq + q^{2}.$$
(19)

This can be obtained from (18) by setting a = p + 2q, b = 2q, c = q. The first solution in Table I corresponds to this case for p = -5, q = 3.

Equations (18) produce solutions to (1) which can be written with at most one term non-positive. Two primitive solutions involving a zero term are obtained by setting (a, b, c) = (1, 10, 14) and (9, 20, 5) which give $(38, 105, 123)^5 = (13, 23, 110, 120)^5$ and $(30, 40, 55)^5 = (6, 19, 49, 51)^5$, respectively.

In conclusion we remark that the general solution of (4) is yet to be obtained; none of the parametric solutions contained here produce. for example, the least solution

$$11 \cdot 2 \cdot 1 (11^2 + 2^2 + 1^2) = 14 \cdot 1 \cdot 1 (14^2 + 1^2 + 1^2)$$

mentioned previously. The general solution of (1) without the rest iction imposed by (2) is also wanting. The least solution of (1) which does not satisfy (2) was found on the computer to be $(1, 1, 3, 24)^5 = (6, 15, 15, 23)^5$.

VIII. EQUAL SUMS OF THREE FIFTH POWERS

A. DISCUSSION

The Diophantine equation

$$A_1^5 + A_2^5 + A_3^5 = B_1^5 + B_2^5 + B_3^5$$
 (1)

was solved in positive integers first by A. Moessner [1] who gave $49^5 + 75^5 + 107^5 = 39^5 + 92^5 + 100^5$. Two parametric solutions were found by Swinnerton-Dyer [2], which result in polynomial solutions of a rather high degree that were not explicitly given. (Dyer did give a single numerical result which appears to be incorrect.) Both Moessner's and Dyer's solutions satisfy (1) together with the additional condition

$$A_1 + A_2 + A_3 = B_1 + B_2 + B_3$$
 (2)

In a computer study [3] the solution of (1) in least integers was found to be $24^5 + 28^5 + 67^5 = 3^5 + 54^5 + 62^5$, which also satisfies (2), as do a great many of the other solutions obtained by search. The least solution of (1) which does not also satisfy (2) is $26^5 + 85^5 + 118^5 = 53^5 + 90^5 + 116^5$, showing that (2) is not necessary in solving (1). In this paper we derive by geometric methods a 3-parameter solution to the system (1), (2), which yields Moessner's numbers as well as other solutions in moderately small integers. A particular version of this solution is given explicitly as a set of polynomials of the ninth degree in a single variable.

Suppose that the Diophantine system (1), (2) has the known solution $A_i = a_i$, $B_i = b_i$, i = 1, 2, 3. If $u = b_3 - a_3$, $v = a_2 - b_2$, $x_0 = a_1 - u$, $y_0 = b_2$, $x_0 = a_3$; then

$$(x + u)^5 + (y + y)^5 + z^5 = (x + y)^5 + y^5 + (z + u)^5$$
 (3)

is the Cartesian equation of a surface S which passes through the point $P_0(x_0, y_0, z_0)$ and contains the parallel lines

$$L_1 : x = y = z$$
, $L_2 : x = y - u = z - v$.

Each rational point P(x, y, z) of S gives a rational solution of (1), (2) through the equations

$$A_1 = x + u$$
 $A_2 = y + v$ $A_3 = z$ $B_1 = x + v$ $B_2 = y$ $B_3 = z + u$. (4)

A solution in integers may be obtained by multiplying A_1, A_2, \ldots, B_3 so as to clear of fractions.

In expanding (3) the terms in x^5 , y^5 , z^5 vanish and therefore S is a surface of the fourth degree. A rational line p_i using through three rational points of S will intersect S again in a fourth rational point. Let T be the plane tangent to S at P_0 and P_j the intersection of T with the line L_j , j=1 or 2. The equation of T is rational, P_j is rational, and thus P_0P_j is a rational line intersecting S in three rational points; that is, twice at P_0 and once at P_j . Hence P_0P_j intersects S in a fourth rational point Q_j , which in some cases gives a new solution to (1). If P_0 falls on L_1 (L_2), the solution degenerates, because then T contains L_1 (L_2) and is parallel to L_2 (L_1). It may also happen that the new solution is trivial. However, for certain initial solutions a_i , b_i new non-trivial solutions are in fact obtained.

The normal to S at P_0 has directions $d_1: d_2: d_3$ where $d_i = a_i^4 - b_i^4$ and the coordinates of $P_1(x_1, y_1, z_1)$, $P_2(x_2, y_2, z_2)$ may be written

$$x_1 = y_1 = z_1 = (x_0 d_1 + y_0 d_2 + z_0 d_3)/(d_1 + d_2 + d_3)$$

 $x_2 = y_2 - u = z_2 - v = x_1 - (d_2 u + d_3 v)/(d_1 + d_2 + d_3)$.

The equation of PoP can be written parametrically as

$$x = x_0 + h_1 t$$
 $y = y_0 + h_2 t$ $z = z_0 + h_3 t$ (5)

for j = 1 or 2, where $h_1 = x_j - x_0$, $h_2 = y_j - y_0$, $h_3 = z_j - z_0$. On substituting (5) into (3) there results an equation of the form

$$c_4t^4 + c_3t^3 + c_2t^2 + c_1t + c_0 = 0$$

in which

$$c_4 = 5 \sum_{i=1}^{3} h_i^4 (a_i - b_i)$$
 $c_3 = 10 \sum_{i=1}^{3} h_i^3 (a_i^2 - b_i^2)$. (6)

Three of the roots of this equation are t = 0, 0, 1 and so the fourth root is $t = -(c_3/c_4) - 1$, which together with (5) gives the coordinates of Q_j .

If the minimal solution of (1) is used as an initial solution, the two resulting new solutions (actually there are several sets corresponding to permutations of the a_i and b_i) involve integers of 17 digits. If instead we attempt to use a trivial initial solution in which the b_i are simply a permutation of the a_i , the new solution is either degenerate or trivial.

However, a trivial initial solution of the type

$$a_1 = p$$
 $a_2 = -p$ $a_3 = r$ $b_1 = q$ $b_2 = r$ $b_3 = -q$ (7)

does produce new solutions. It is sufficient to use Q_2 , to take r > 0, p > 0, |q| > p and have p, q, r all distinct in magnitude. Some results for small integer values of the arguments p, q, r are given in Table XXIV; it will be noted that Moessner's solution is the smallest obtained.

The foregoing provides an implicit parametric solution of (1), (2) in three integer variables (or two rational variables), but does not give the results explicitly in a form which facilitates the calculation of numerical solutions. Accordingly, a specialized solution was computed for (7) with p = -2, q = 1, using the case j = 2 of (5). After clearing of fractions, the result is

$$A_{1} = -2r^{8} + 10r^{7} + 20r^{6} + 20r^{5} + 34r^{4} - 10r^{3} - 270r^{2} - 20r - 682$$

$$A_{2} = 2r^{8} + 10r^{7} - 20r^{6} + 20r^{5} - 34r^{4} - 10r^{3} + 270r^{2} - 20r + 682$$

$$A_{3} = r^{9} - 22r^{5} - 125r^{3} - 79r$$

$$B_{1} = r^{8} + 10r^{7} - 10r^{6} + 20r^{5} - 92r^{4} - 160r^{3} - 15r^{2} - 320r + 341$$

$$B_{2} = r^{9} - 22r^{5} + 175r^{3} + 521r$$

$$B_{3} = -r^{8} + 10r^{7} + 10r^{6} + 20r^{5} + 92r^{4} - 160r^{3} + 15r^{2} - 320r - 341$$

The values of these polynomials for several small rational arguments (after clearing of fractions and removing any common factor) are presented in Table XXV.

In conclusion we note that the solutions obtained can be put in one of the two forms $A^5 + B^5 + C^5 = D^5 + E^5 + F^5$ or $A^5 + B^5 = C^5 + D^5 + E^5 + F^5$ where A, B, C, D, E, F are positive integers. The last three entries in Table I are examples of the latter type.

IX. EQUAL SUMS OF BIQUADRATES

A. DISCUSSION

Solutions of the Diophantine equation $A^4+B^4=C^4+D^4$ in least integers have been obtained by several authors (References 1, 2, 3, 4). The term <u>primitive</u> denotes a solution for which unity is the greatest common divisor of all the numbers A, B, C, D. A CDC 3200 computer program was written to search exhaustively for primitives, yielding the 31 solutions listed in Table XXVI. The range covered is $A^4+B^4<7.885\times10^{15}$. The first six solutions were identified in Reference 3 and the seventh is cited in Reference 1.

Euler (Reference 1) gave a two-parameter algebraic solution which can be written

$$A=f(x, y)$$
 $B=f(y, -x)$ $C=f(-x, y)$ $D=f(y, x)$

where $f(x, y)=2x^7-x^6y+20x^5y^2+17x^4y^3+2x^3y^4+17x^2y^5+8xy^6-y^7$. The primitives corresponding to i=1,7, and 14 of Table XXVI are special cases of this solution for the arguments (x, y)=(3, 1), (2, 1), and (5, 1), respectively.

The computer program generated all values of $N=A^4+B^4$ in ascending order by controlling the advance of a series of pairs of values A, B while monitoring N for coincidences. To advance from a given starting value of N, all integers A for which $N/2 \le A^4 \le N$ were considered; for each A a corresponding B was chosen as the largest integer in the range $0 \le B \le A$ for which $A^4+B^4 \le N$. Then the smallest value $A_1^4+B_1^4$ in the set was found and B_1 was advanced if $B_1 < A_1$, the lower limit on A was advanced if $B_1 = A_1$, and the upper limit on A was advanced if $B_1 = 0$.

A similar computer program generated sums of three biquadrates $A^4+B^4+C^4$ in ascending order and found the least triple coincidence to be

$$811,538=29^{4}+17^{4}+12^{4}=28^{4}+21^{4}+7^{4}=27^{4}+23^{4}+4^{4}$$

It was discovered quite by chance (using a computer program which decomposes numbers into sums of biquadrates by trial) that for the N_i of Table XXVI

Table XXVI $\label{eq:primitive Solutions of N=A^4+B^4=C^4+D^4 }$ Primitive Solutions of N=A^4+B^4=C^4+D^4 }

X. GEOMETRIC ASPECTS OF EULER'S DIOPHANTINE EQUATION $A^4 + B^4 = C^4 + D^4$

A. INTRODUCTION

Euler [1], [2] gave two parametric solutions of the Diophantine equation

$$A^4 + B^4 = C^4 + D^4. (1)$$

but the general solution is presently unknown. We give a geometric derivation of Euler's solutions and apply the geometric methods to obtain a new parametric solution, several new particular solutions and two complex parametric solutions. Related work by other investigators is also discussed. In a previous study [3], [4], the 46 smallest primitive solutions of (1) (those in which any factor common to A, B, C, D has been removed) were found by generating and sorting integers of the form $a^4 + b^4$ on a digital computer. These primitive solutions will be referred to as σ_1 , σ_2 , ..., ranked in order of increasing magnitude of the common sum $A^4 + B^4$. We say $\sigma = (a, b, c, d)$ is a solution if A = a, B = b, C = c, D = d satisfies (1). For example, $\sigma_1 = (158, 59, 134, 133)$, $\sigma_7 = (1203, 76, 1176, 653)$, $\sigma_{14} = (3494, 1623, 3351, 2338)$, $\sigma_{39} = (12231, 2903, 10381, 10203)$, and $\sigma_{46} = (15109, 581, 14723, 8461)$.

B. EULER'S ALGEBRAIC SOLUTION

Euler treated (1) by setting

$$A = p + q$$
 $B = r - s$ $C = p - q$ $D = r + s$ or (2.1)

$$2p = A + C$$
 $2q = A - C$ $2r = D + B$ $2s = D - B$ (2.2)

which reduces (1) to

$$pq (p^2 + q^2) = rs (r^2 + s^2).$$
 (3)

To each set of four positive integers A, B, C, D satisfying (1) there correspond 64 sets of integers (p, q, r, s) satisfying (3) obtained by using (2.2) and generating trivially different sets such as (p, q, s, r), (q, p, r, s), (p, -q, r, -s). A quite distinct solution of (3) is obtained by interchanging C and D in (2.1):

$$A = p_1 + q_1$$
 $B = r_1 - s_1$ $C = r_1 + s_1$ $D = p_1 - q_1$ (4.1)

$$2p_1 = A + D$$
 $2q_1 = A - D$ $2x_1 = C + B$ $2s_1 = C - B$ (4.2)

and there are similarly 64 sets such as (p_1, q_1, r_1, s_1) which satisfy (3). For σ_1 we have (p, q, r, s) = (146, 12, 96, 37) and $(2p_1, 2q_1, 2r_1, 2s_1) =$ (291, 25, 193, 75). The paired solutions to (3) are related by the equations

$$2p_{1} = p + q + r + s$$

$$2p = p_{1} + q_{1} + r_{1} + s_{1}$$

$$2q_{1} = p + q - r - s$$

$$2q = p_{1} + q_{1} - r_{1} - s_{1}$$

$$2r_{1} = p - q + r - s$$

$$2r = p_{1} - q_{1} + r_{1} - s_{1}$$

$$2s_{1} = p - q - r + s$$

$$2s = p_{1} - q_{1} - r_{1} + s_{1}.$$
(5)

On substituting z = q/s, v = (rs/pq) - 1, (3) becomes

$$(z^{2}-1)^{2}+v(3z^{4}-4z^{2}+1)+v^{2}(3z^{4}-6z^{2})+v^{3}(z^{4}-4z^{2})-v^{4}z^{2}=\left[\frac{s}{p}(z^{2}-v-1)\right]^{2}$$
 (6)

and Euler made the quartic function of v on the left-hand side of (6) a square in two ways. First it was equated to $[(z^2-1) + fv + gv^2]^2$ and f and g were chosen to make the coefficients of v and v in the resulting equation vanish. A rational solution of v as a function of z results. Euler [1] did not give the final algebraic result explicitly but did give the numerical solutions (2061283, 1584749, 2219449, 555617) and σ_{39} for z = 2 and z = 3, respectively. By completing the polynomial calculation, we find a solution of the 13th degree:

$$p = 3 (z^{2}-1)^{2} (9z^{8}-44 z^{6} + 190 z^{4} + 100 z^{2} + 1)$$

$$q = z (z^{12} - 214 z^{10} - 2481 z^{8} - 2804 z^{6} - 2481 z^{4} - 214 z^{2} + 1)$$

$$r = 3z (z^{2}-1)^{2} (z^{8} + 100 z^{6} + 190 z^{4} - 44 z^{2} + 9)$$

$$s = z^{12} - 214 z^{10} - 2481 z^{8} - 2804 z^{6} - 2481 z^{4} - 214 z^{2} + 1.$$
(7)

These polynomials do not seem to have been previously recorded. In the second approach the quartic function in (6) was equated to $[(1+dv)(z^2-v-1)]^2$ and upon removing the common factor (z² - v - 1) there results $v^{3}(z^{2}+d^{2})+v^{2}(3z^{2}-d^{2}z^{2}+d^{2}+2d)+v(3z^{2}-2dz^{2}+2d+1)=0$

This leads to the well known solution [2] of the 7th degree:

$$p = 2 (4z^{6} + z^{4} + 10z^{2} + 1) r = 2z (z^{6} + 10z^{4} + z^{2} + 4)$$

$$q = -z (z^{2} + 1) (z^{4} - 18z^{2} + 1) s = -(z^{2} + 1) (z^{4} - 18z^{2} + 1)$$
(8)

which produces σ_1 , σ_7 , σ_{14} for z = 3, 2, 5. In addition to the two parametric solutions, Euler [5] found the particular solution σ_5 = (542, 103, 514, 359) by making special assumptions.

C. GEOMETRIC INTERPRETATION

If we set

$$x = p/s y = r/s z = q/s (9)$$

then (3) becomes

$$y^3 + y = x^3z + xz^3. ag{10}$$

For a fixed rational z we may interpret (10) as the Cartesian equation of a cubic curve K in the xy plane, symmetric with respect to the origin and passing through the rational point P with coordinates x = 1, y = z. Each rational point on K corresponds to a solution of (3) through the relations p = xs, q = zs, r = ys for arbitrary s. The point P gives the trivial solution p = s, q = r. Now a straight line in the xy plane intersects K in one or three real points (possibly at infinity) so the tangent to K at $P_0(x_0, y_0)$ intersects K again in $P_1(x_1, y_1)$. If P_0 is a rational point, the tangent has a rational equation, and as x_0, x_0, x_1 are then the three zeros of a rational cubic polynomial, P_1 is also a rational point on K.

The tangent at P_0 has slope $t = (z^3 + 3x_0^2z)/(3y_0^2 + 1)$ and the coordinates of P_1 are $x_1 = -2x_0 - [3t^2(y_0 - tx_0)/(t^3 - z)]$, $y_1 = t(x_1 - x_0) + y_0$. By setting $x_0 = 1$, $y_0 = z$ we find

$$x_1 = \frac{-2 (4z^6 + z^4 + 10 z^2 + 1)}{(z^2 + 1) (z^4 - 18 z^2 + 1)} \qquad y_1 = \frac{-2z (z^6 + 10 z^4 + z^2 + 4)}{(z^2 + 1) (z^4 - 18 z^2 + 1)}$$

and if $s = -(z^2 + 1)(z^4 - 18z^2 + 1)$, the solution (8) results.

If $z = m^3$, K has the rational asymptote y = mx and a line through $P_0(x_0, y_0)$

parallel to this asymptote must intersect K again in a rational point P_2 (x_2 , y_2). We find

$$x_2 = [1 + (y_0 - mx_0)^2]/3m^2$$
, $y_2 = m (x_2 - x_0) + y_0$ and if $x_0 = 1$, $y_0 = z$ then $x_2 = (m^6 - 2m^4 + m^2 + 1)/3m^2$, $y_2 = m (m^6 + m^4 - 2m^2 + 1)/3m^2$. Setting $s = 3m^2$ there results the following solution to (3):

$$p = m^6 - 2m^4 + m^2 + 1$$
 $r = m (m^6 + m^4 - 2m^2 + 1)$
 $q = 3m^5$ $s = 3m^2$ (11)

This solution was given by A. Gérardin [6] and an algebraic derivation of it due to P. S. Dyer [7] can be found also in Hardy and Wright [8]. The solutions to (1) produced by (11) are in fact the same as those given by (8). The explanation is that the rational transformation m = (z + 1)/(z - 1) carries (p, q, r, s) of (11) into polynomials proportional to $(-s_1, r_1, p_1, -q_1)$ obtained by applying the transformation (5) to (p, q, r, s) of (8). If we reverse this procedure for Euler's first solution, applying (5) to (7) and then substituting z = (m + 1)/(m - 1), we get the following solution which is simpler than, but equivalent to, (7):

$$p = m (m^{12} + 2m^{10} - 3m^8 + 7m^6 - 12m^4 + 5m^2 + 1)$$

$$q = m^{12} - 4m^{10} + 3m^8 + 4m^6 - 6m^4 - m^2 + 1$$

$$r = m (m^{12} - m^{10} - 6m^8 + 4m^6 + 3m^4 - 4m^2 + 1)$$

$$s = m^{12} + 5m^{10} - 12m^8 + 7m^6 - 3m^4 + 2m^2 + 1$$
(12)

This solution can also be found geometrically using the fact that a line joining two rational points P_1 (x_1 , y_1), P_2 (x_2 , y_2) of K intersects K in a third rational point P_3 (x_3 , y_3). The slope of the line is $t = (y_2 - y_1)/(x_2 - x_1)$ and $x_3 = -[x_1 + x_2 + 3t^2 (y_1 - tx_1)/(t^3 - z)]$, $y_3 = t (x_3 - x_1) + y_1$. Given any initial solution (p_0 , q_0 , r_0 , s_0) of (3), take $x_1 = 1$, $y_1 = z = q_0/s_0$, $x_2 = p_0/s_0$, $y_2 = r_0/s_0$. The slope t is then $(r_0 - q_0)/(p_0 - s_0)$. If we take (p_0 , q_0 , r_0 , s_0) to be the polynomials (s. r. q. p.) of (11), then t = m and the new rational point (x_3 , y_3) gives a solution equivalent to (12). A new solution of the 19th degree is obtained by taking (p_0 , q_0 , r_0 , s_0) = (r. s. q. p.) from (11), and $x_1 = -1$, $y_1 = -z = -q_0/s_0$, $x_2 = p_0/s_0$, $y_2 = r_0/s_0$ which leads to

 $p = m^{19} - m^{18} - 3m^{17} - 3m^{16} + 21m^{15} - 9m^{14} - 44m^{13} + 74m^{12} - 39m^{11}$ $-21m^{10} + 84m^{9} - 132m^{8} + 115m^{7} - 73m^{6} + 45m^{5} - 21m^{4} + 12m^{3} - 6m^{2} + m - 1$ $q = 3m^{2} (m^{12} - 4m^{10} + 18m^{9} - 36m^{8} + 27m^{7} + m^{6} - 9m^{5} + 9m^{4} - 9m^{3}$ $+ 5m^{2} + 1)$ $r = 3m^{2} (m^{15} - 3m^{14} - m^{13} + 11m^{12} - 12m^{11} + 4m^{10} + 10m^{9} - 30m^{8} + 39m^{7}$ $- 37m^{6} + 41m^{5} - 33m^{4} + 16m^{3} - 8m^{2} + 3m - 1)$ $s = (m^{6} - 2m^{4} + m^{2} + 1) (m^{12} - 4m^{10} + \frac{1}{2}8m^{9} - 36m^{8} + 27m^{7} + m^{6} - 9m^{5}$ $+ 9m^{4} - 9m^{3} + 5m^{2} + 1).$ (13)

These polynomials give σ_1 for m=-1 and new solutions such as (A, B, C, D) = (134413, 34313, 114613, 111637), (1057167, 552059, 1054067, 545991) for m=2, -2. The particular result for m=2 was found by E. Fauquembergue [9] using another algebraic method.

B. Segre [12] has given a general geometric treatment of fourth order Diophantine equations which correspond to quartic surfaces containing rational lines. In his paper two geometric transformations are introduced which for (1) lead to Euler's solution (8) and more generally to a discontinuous infinity of rational parametric solutions, not given explicitly.

D. COMPLEX SOLUTIONS

The rational complex points x = iz, y = i lie on K and the tangent at each of these points has a second rational intersection with K, giving the following solutions to (3) of the 5th degree in Gaussian integers:

$$p = iz (z^{4} - 2)$$
 $r = i (-2z^{4} + 1)$
 $q = z (z^{4} + 1)$ $s = z^{4} + 1$ (14. 1)

$$p = -iz(z^{4} + 2)$$
 $r = -i(2z^{4} + 1)$ (14.2)
 $q = z(z^{4} - 1)$ $s = z^{4} - 1$

E. PARTICULAR SOLUTIONS

By starting with any of the polynomial solutions already given and employing the geometric techniques discussed here, further parametric

solutions may be obtained. Whether or not such procedures eventually yield all rational soultions to (1) is not apparent. The primitives σ_2 = (239, 7, 227, 157) and σ_3 = (292, 193, 257, 256) found by A. Werebrusow [10] are not produced by Euler's formulas (nor are any of the other computer-derived solutions except σ_1 , σ_7 , σ_{14} , σ_{39}), but are nevertheless geometrically derivable one from the other. By taking z = 2/25 in (10), the two rational points x = 233/75, y = 82/75 and x = -274/225, y = -32/225 on K correspond to σ_2 , σ_3 and the line joining these points intersects K in the trivial point x = -1, y = -2/25. A number of similar relationships were found to hold among certain sets of the smallest known primitives, specifically (σ_2 , σ_3 , σ_{11} , σ_{18}), (σ_4 , σ_{13} , σ_{22}), (σ_6 , σ_{45}), (σ_{16} , σ_{40}), (σ_{19} , σ_{41}), and (σ_{36} , σ_{46}).

The geometric methods can be applied to particular numerical solutions and in some cases result in new solutions which do not involve overly large integers. Examples are (A, B, C, D) = (15265, 6101, 13085, 12743), (27407, 758, 27374, 7217), and (31731, 5468, 27661, 25596) derived from σ_{25} , σ_{38} , and σ_{15} , respectively.

F. ANOTHER SOLUTION

T. Hayashi [11] showed that every solution of Diophantine equation

$$3u^4 + v^4 = w^2 ag{15}$$

leads to a solution to (1). We can express his result by stating that if u, v, w satisfy (15), then

$$p = 2u^{3} (2u^{4} + v^{4})$$
 $r = 2u^{6}v$
 $q = uv^{4}w$ $s = vw (2u^{4} + v^{4})$

satisfy (3). Several systems are known which produce from one solution u_1 , v_1 , w_1 to (15) a new solution u_2 , v_2 , w_2 ; for example,

$$u_2 = 2u_1v_1w_1$$
 $v_2 = 2v_1^4 - w_1^2$ $w_2 = w_1^4 + 12u_1^4v_1^4$.

The least solutions to (15) are (u, v, w) = (1, 1, 2), (2, 1, 7), and (3, 11, 122) which yield, respectively (A, B, C, D) = (2, 1, 1, 2), (542, 103, 514, 359) = σ_5 , and (4970416, 1139811, 4962397, 1539492).
